

超伝導体検出器

– SOI技術との融合による遠赤外一光子検出 STJ 開発 –

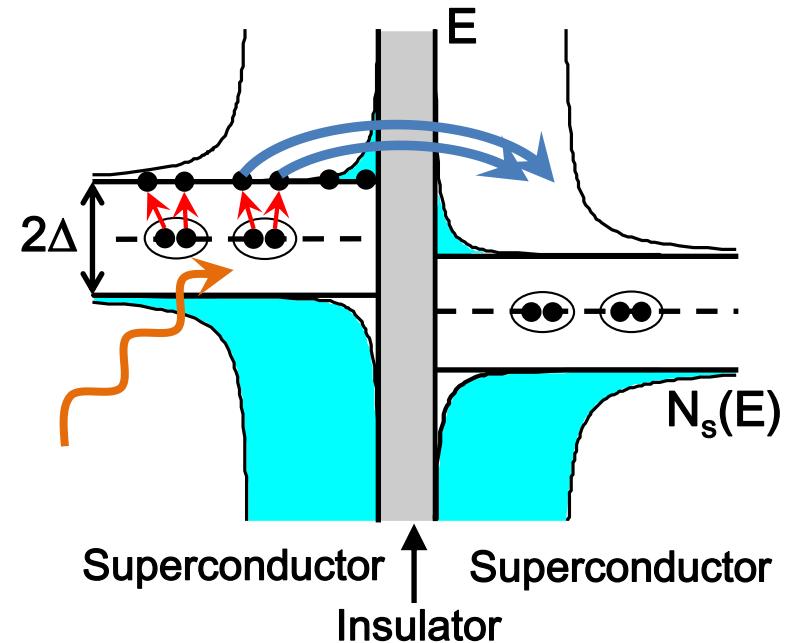

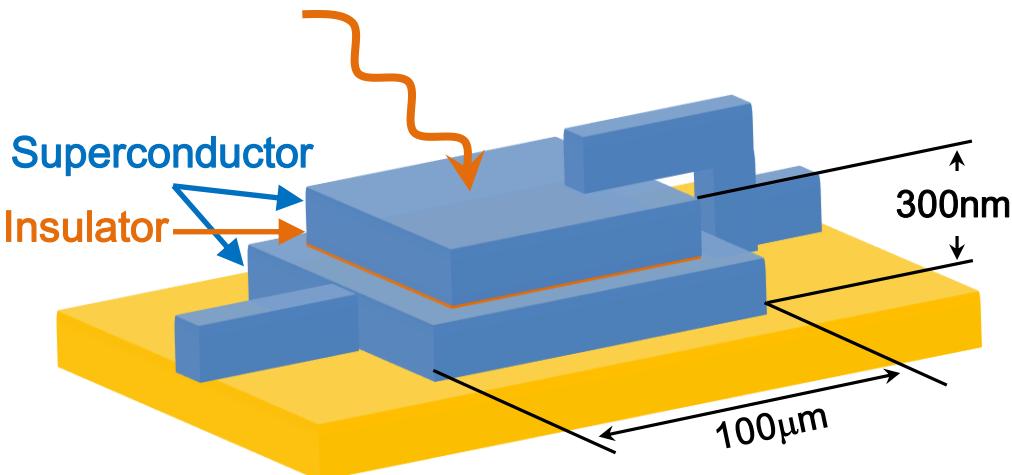

2015年11月30日 /光量子計測器開発推進室発足会議
武内勇司 (筑波大 数理物質融合科学センター)

on behalf of Neutrino Decay Collaboration

S. H. Kim, K. Takemasa, K. Kiuchi, K. Nagata, K. Kasahara, K. Moriuchi, R. Senzaki, S. Murakami, S. Yagi (U. Tsukuba), S. Matsuura (Kwansei Gakuin U.), H. Ikeda, T. Wada, K. Nagase (JAXA/ISAS), H. Ishino, A. Kibayashi (Okayama U.), S. Mima (RIKEN), T. Yoshida, R. Hirose, Y. Kato, C. Asano, T. Nakamura (U. Fukui), Y. Kato (Kinki U.), Y. Arai, M. Hazumi, I. Kurachi (KEK), S. Shiki, M. Ukibe, G. Fujii, M. Ohkubo (AIST), E. Ramberg, J. H. Yoo, M. Kozlovsky, P. Rubinov, D. Sergatskov (FNAL), S. B. Kim (Seoul National U.) and S. Kawahito (Shizuoka U.)

Superconducting Tunnel Junction (STJ)

- Superconductor / Insulator /Superconductor
Josephson junction device

接合面を挟んで電位差($|V| < 2\Delta$)を印加.

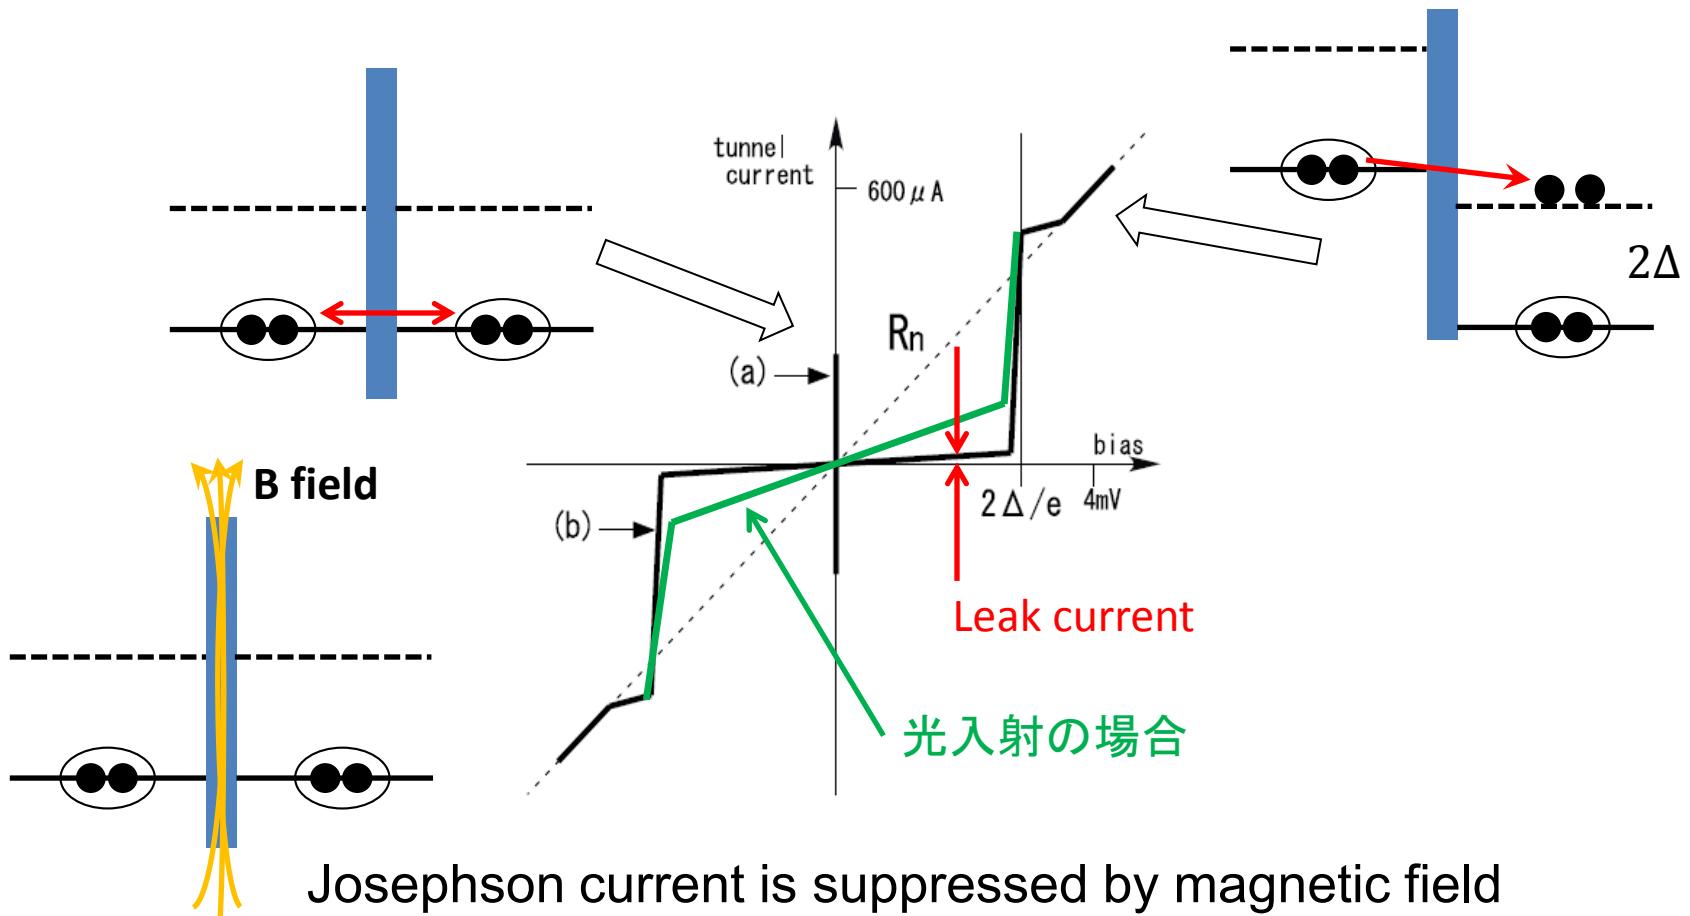

超伝導体に吸収された光子のエネルギーにより複数のクーパー対が解離(励起)し、生成された準粒子によって、エネルギーに比例したトンネル電流が発生.

Δ : Superconducting gap energy

- 超伝導ギャップ(Δ)は遠赤外フォトンのエネルギーよりもずっと小さい → 原理的には、遠赤外域一光子を検出可能
- $\sim \mu s$ 程度の比較的高速なパルス応答(Nbの場合) → 光子計数することでS/Nの著しい向上

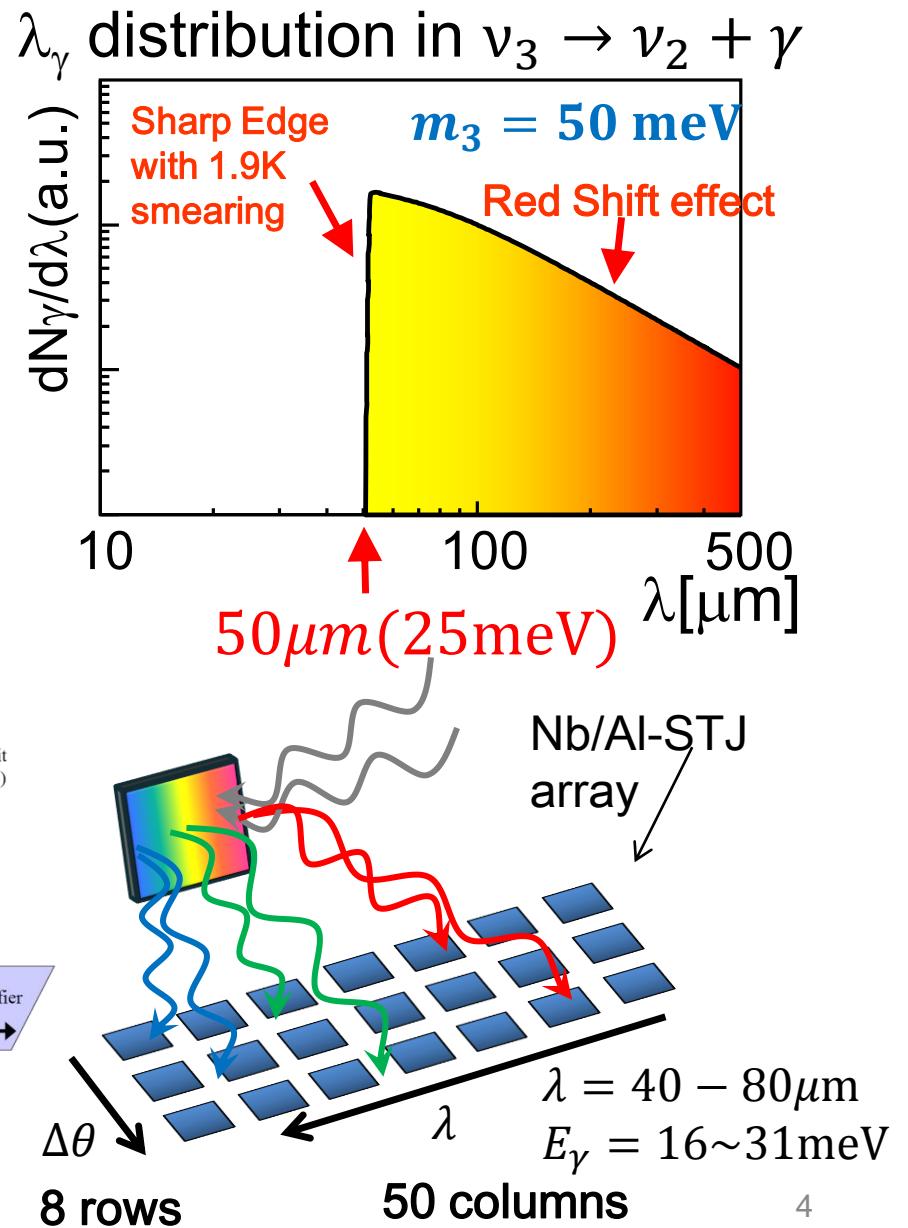

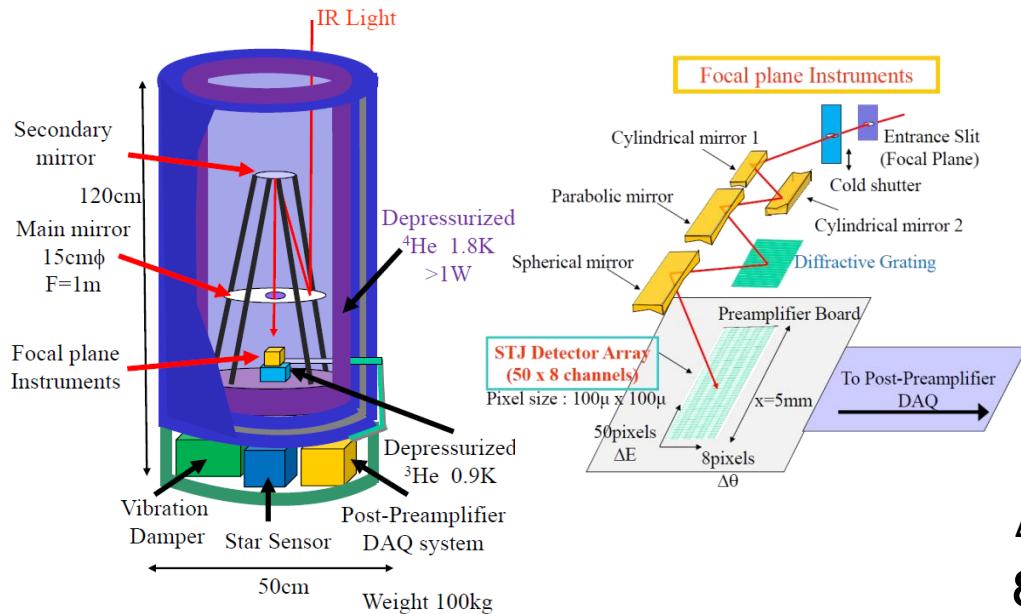

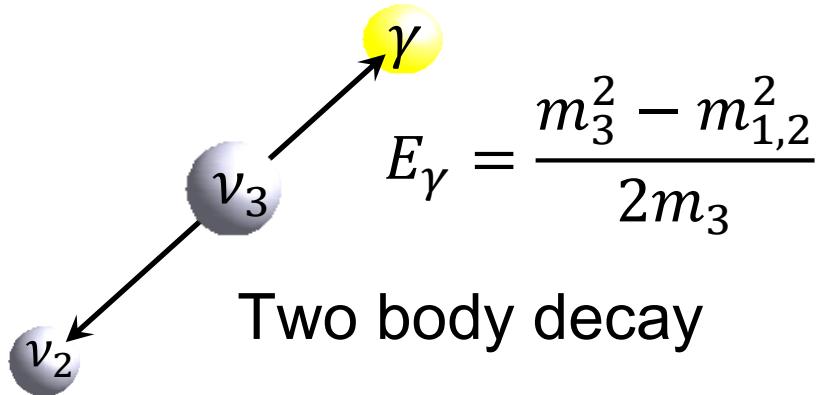

STJ I-V 特性

- Sketch of a current-voltage (I-V) curve for STJ
- The Cooper pair tunneling current (DC Josephson current) is seen at $V = 0$, and the quasi-particle tunneling current is seen for $|V| > 2\Delta$

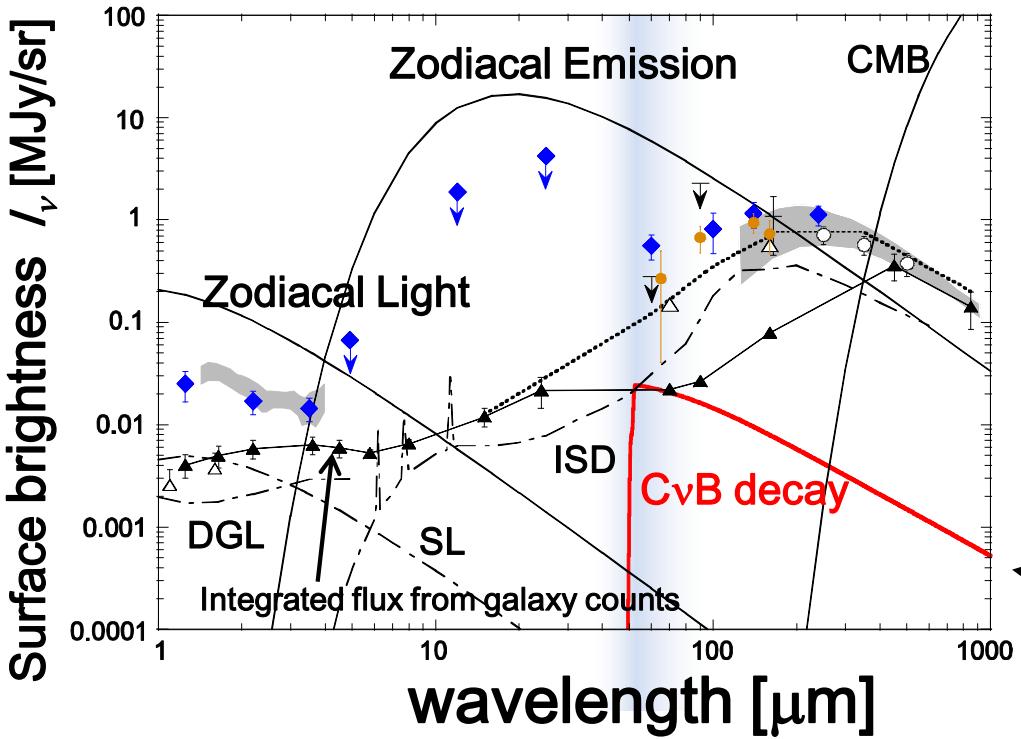

宇宙背景ニュートリノ崩壊探索への応用

$\nu_3 \rightarrow \nu_{1,2} + \gamma$
in the ν_3 rest frame

宇宙背景ニュートリノ崩壊探索への応用

Telescope parameters

- Main mirror
 - $D=15\text{cm}, F=1\text{m}$
- detector
 - 波長 $0.8\mu\text{m}$ あたり
 - $100\mu\text{m} \times 100\mu\text{m} \times 8$ pixels
 - 視野角 : $8 \times 10^{-8} \text{ sr}$

$$\tau = 1 \times 10^{14} \text{ yrs}$$

- Neutrino decay ($m_3 = 50 \text{ meV}, \tau_\nu = 1 \times 10^{14} \text{ yrs}$): $I_\nu = 25 \text{ kJy/sr}$
 - $3.3 \times 10^{-20} \text{ W / 8pixels @ } \lambda=50\mu\text{m}$
- 200sec の測定でこれを検出

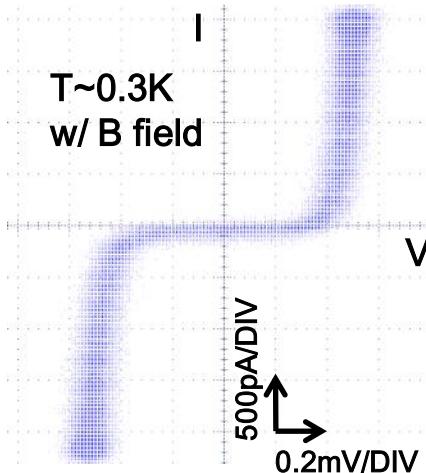

→ 検出器の性能として最低でも $\text{NEP} < 6.6 \times 10^{-19} \text{ W / } \sqrt{\text{Hz}}$ が必要

 - 実際には、本物のフォトンによるバックグラウンド(Zodiacal emission)があるので、更に1 order 位低い必要がある ($\text{NEP} < 1 \times 10^{-19} \text{ W / } \sqrt{\text{Hz}}$)

産総研 CRAVITY 製 Nb/Al-STJ

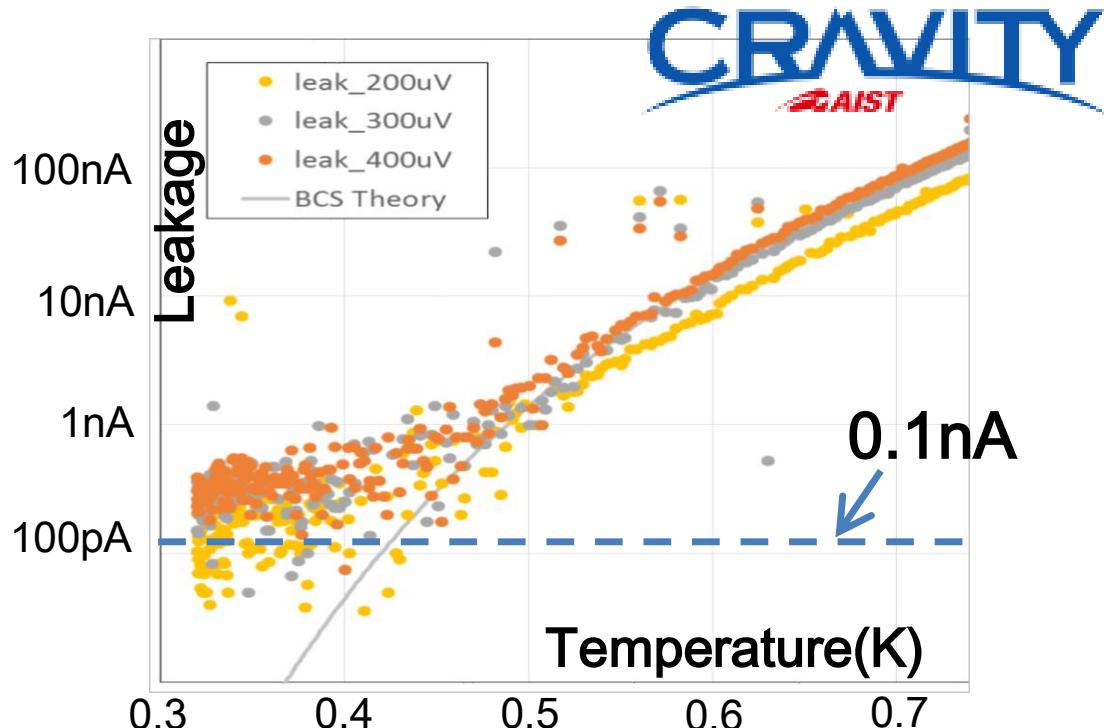

M. Ukibe et al., Jpn. J. Appl. Phys. 51, 010115 (2012)

M. Ohkubo et al., IEEE Trans. Appl. Super, 24, 2400208 (2014)

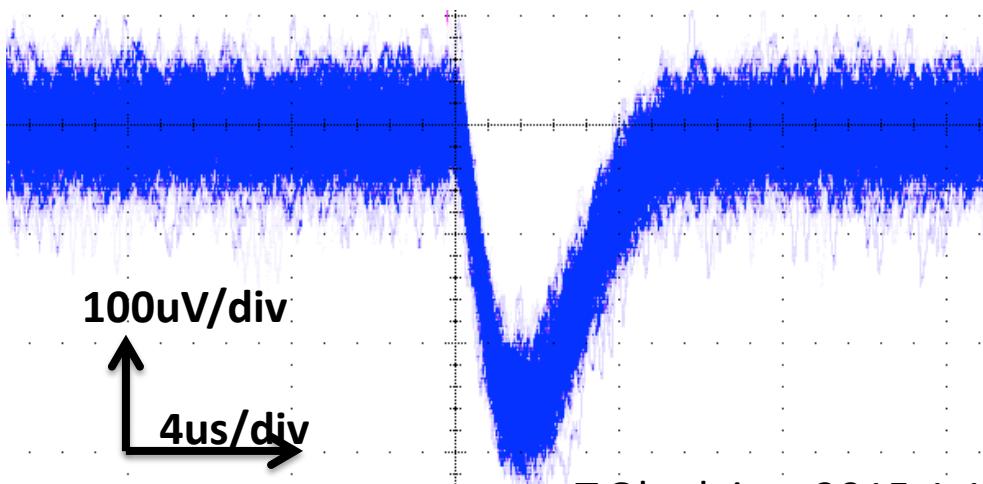

$50\mu\text{m} \times 50\mu\text{m}$ Nb/Al-STJ
fabricated in CRAVITY at AIST

- $I_{\text{leak}} \sim 0.2\text{nA}$ を達成
- 更に小さな junction size のものでテスト中
- リーク電流のショットノイズ由来のNEPは，リーク電流 $i_L = 50\text{pA}$, 超伝導ギャップエネルギー $\Delta = 0.6\text{meV}$, トラッピングゲイン $G = 10$ とすると

$$\text{NEP} = \frac{1.7\Delta}{G} \sqrt{\frac{2i_L}{e}} \sim 4 \times 10^{-19} W/\sqrt{\text{Hz}}$$

STJパルス光応答特性

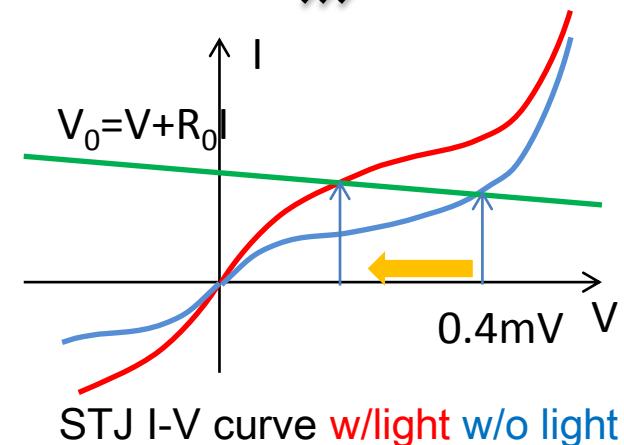

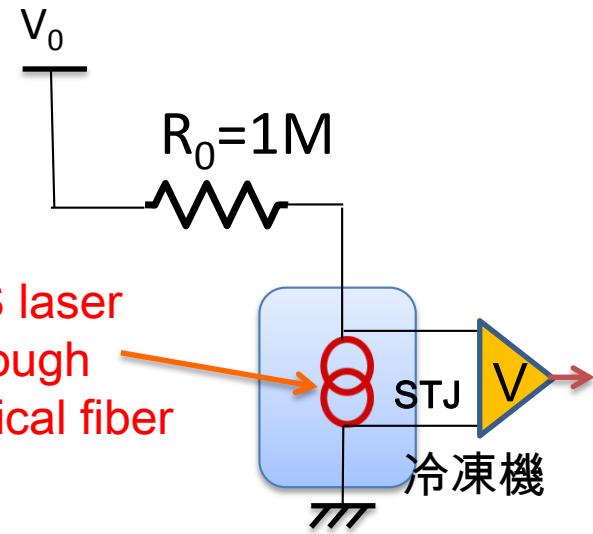

100uV/div
4us/div

T.Okudaira, 2015.1.16

可視光(465nm)レーザーパルス応答性(AIST製
Nb/AI-STJ 100um角)

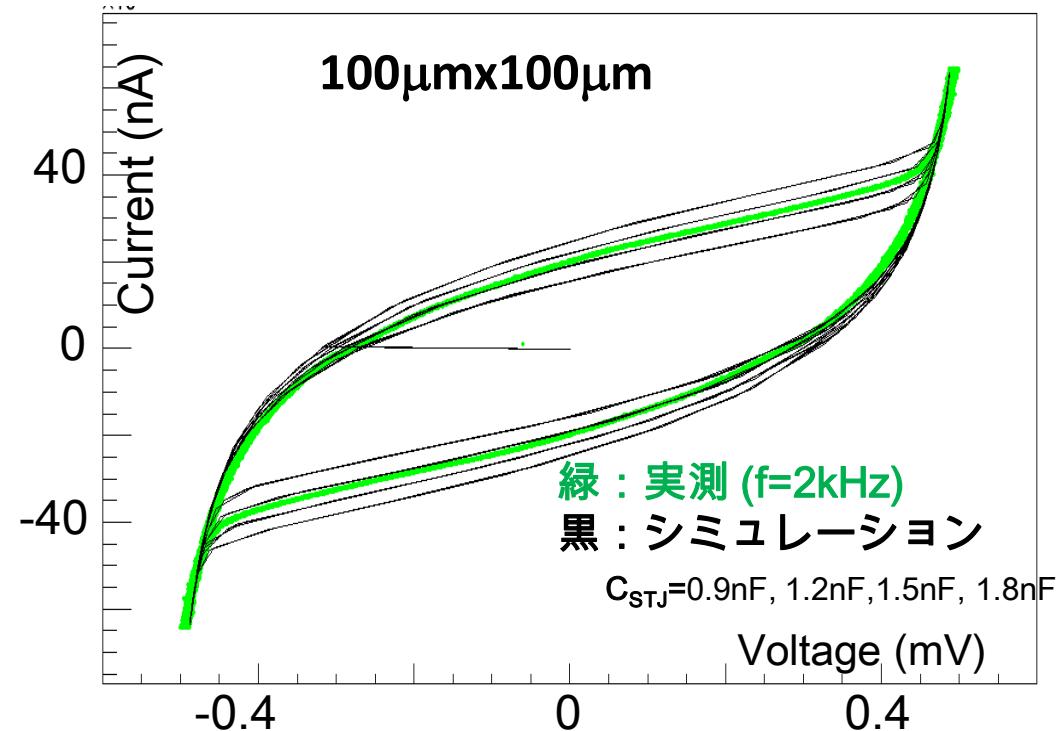

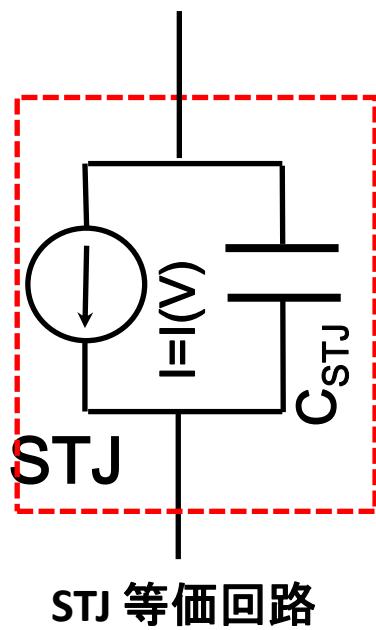

STJ 応答信号時定数: 立下り ~1μs, 立上り~2μs
(もしくは, これより早い)

定電流モードの回路(右上)で測定

- Nb/AI-STJは, ~1μs という比較的早い応答速度
- 光子計数を行えば, 実効的なNEPは劇的に改善可能
 - 但し読み出し系の帯域は>1MHzを確保する必要あり

STJ キャパシタンス測定

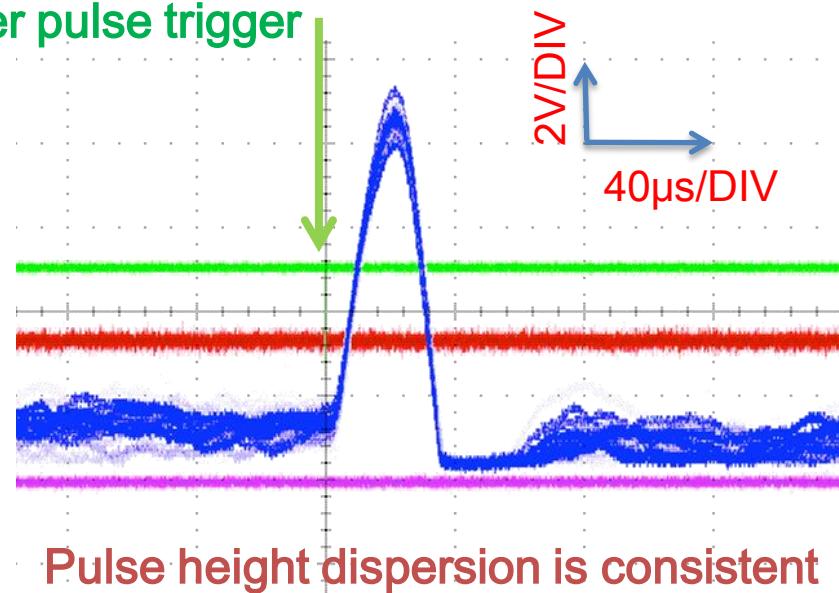

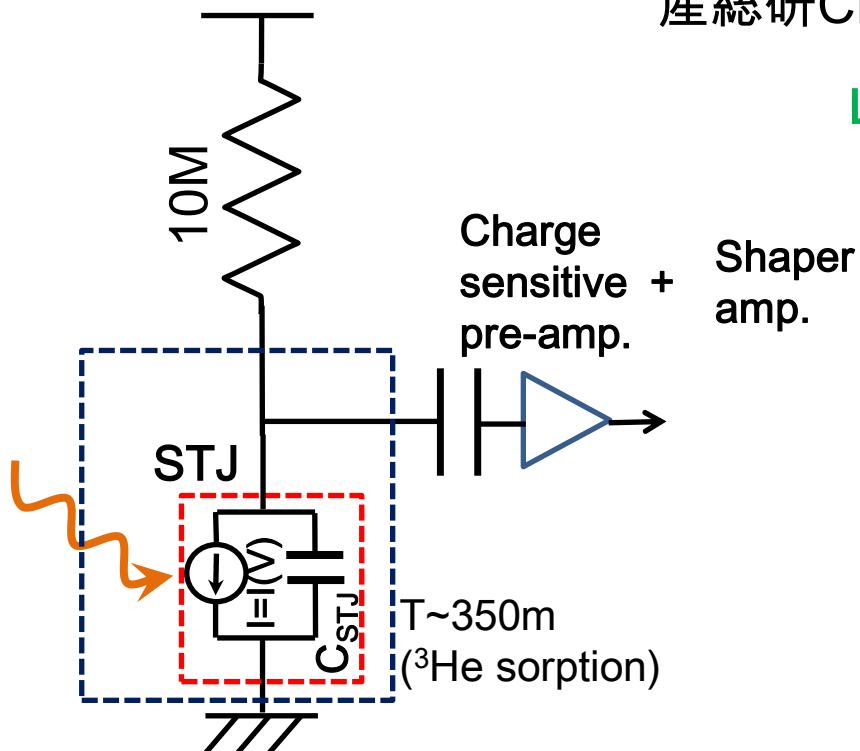

STJ は，junction size に比例したキャパシタンス

- STJのI-V測定からSTJのキャパシタンスを測定
- SIS接合面の面積に比例する成分： $\sim 34\text{fF}/\mu\text{m}^2$
- ➔ $20\mu\text{m}$ 角のSTJでも 14pF
- ➔ 低入カインピーダンスの電荷積分型アンプでの読み出しが必要

100x100 μm^2 Nb/AI-STJ response to 465nm multi-photons

産総研CRAVITY製100x100 μm^2 Nb/AI-STJ

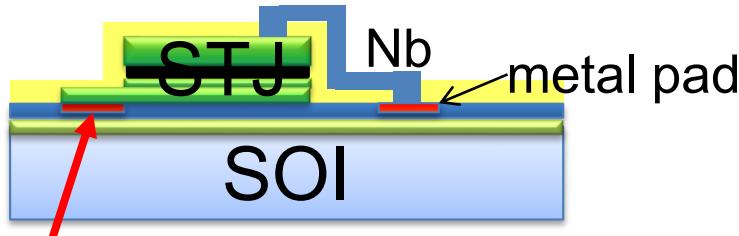

Nb/AI-STJ の低入力インピーダンス電荷積分アンプ読出

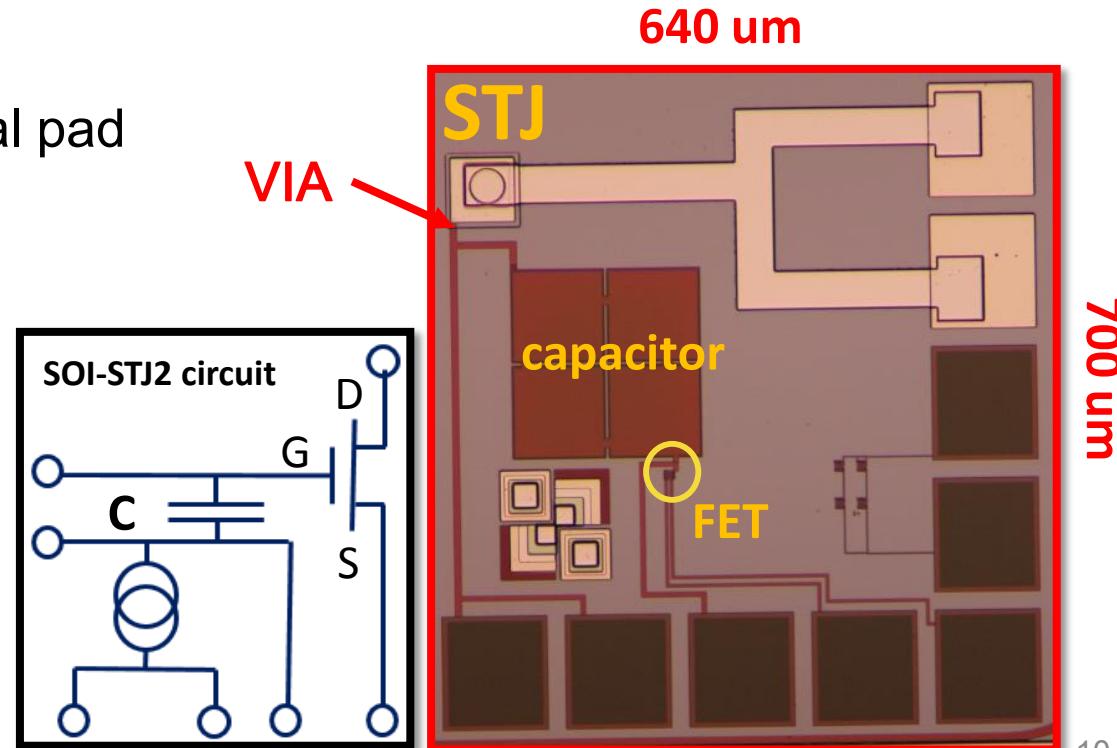

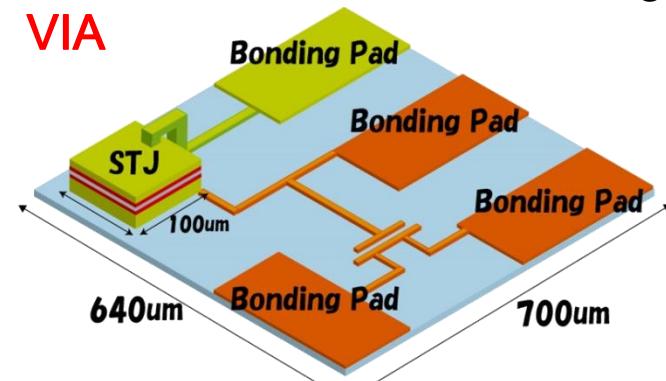

- 可視光パルス(波長465nm)に対する応答
- 室温に置かれた電荷積分型のアンプでの読出
 - 観測した出力電荷量は、およそ10光子の検出に対応
- 一光子検出には、読み出し系のS/N改善が必要
→極低温電荷積分型アンプの開発

Development of SOI-STJ

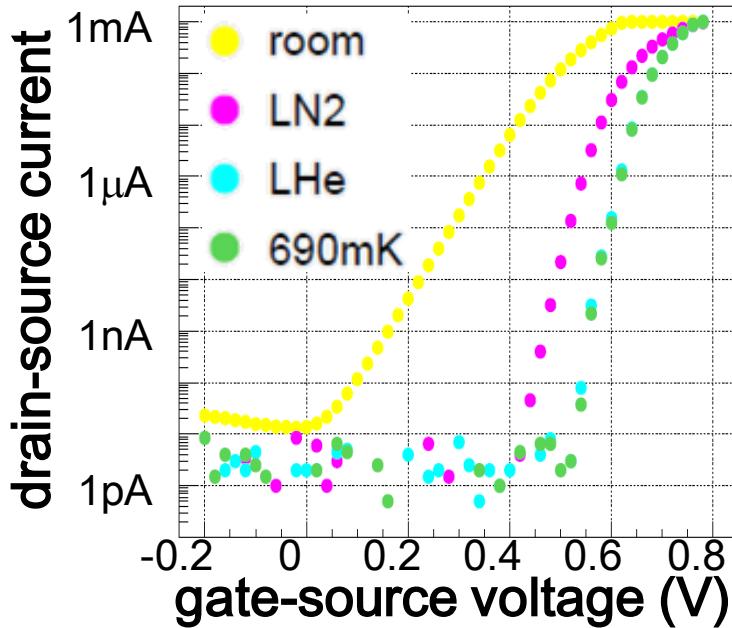

- SOI: Silicon-on-insulator
 - CMOS in FD-SOI is reported to work at 4K by T. Wada (JAXA), et al.
J Low Temp Phys 167, 602 (2012)
- SOI と STJ の融合 (SOI回路一体型 STJ の基礎研究)
 - STJ layers are fabricated **directly on** a SOI pre-amplifier board and cooled down together with the STJ
- Started test with Nb/AI-STJ on SOI with p-MOS and n-MOS FET

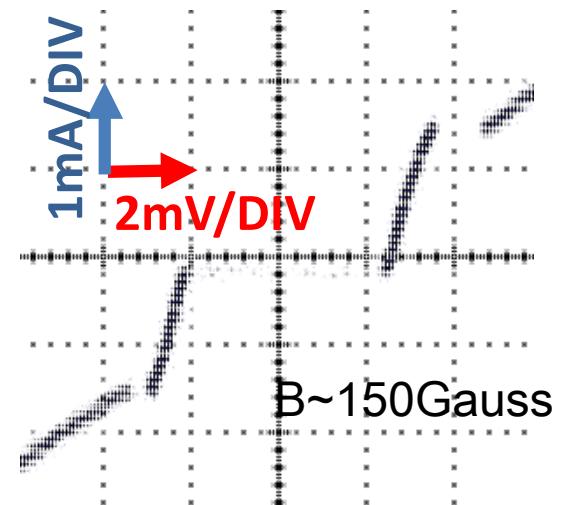

STJ lower layer has electrical contact with SOI circuit through
VIA

SOI上にSTJを形成後の特性

nMOS-FET in FD-SOI wafer on which a STJ is fabricated at KEK

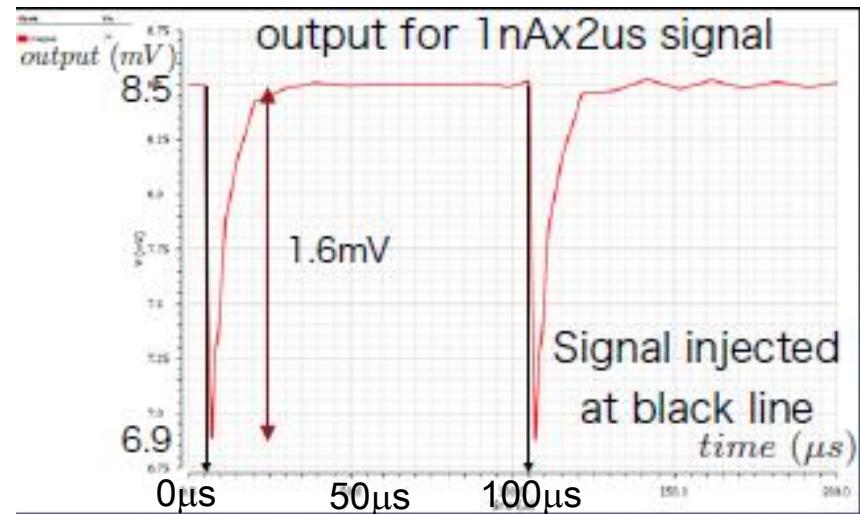

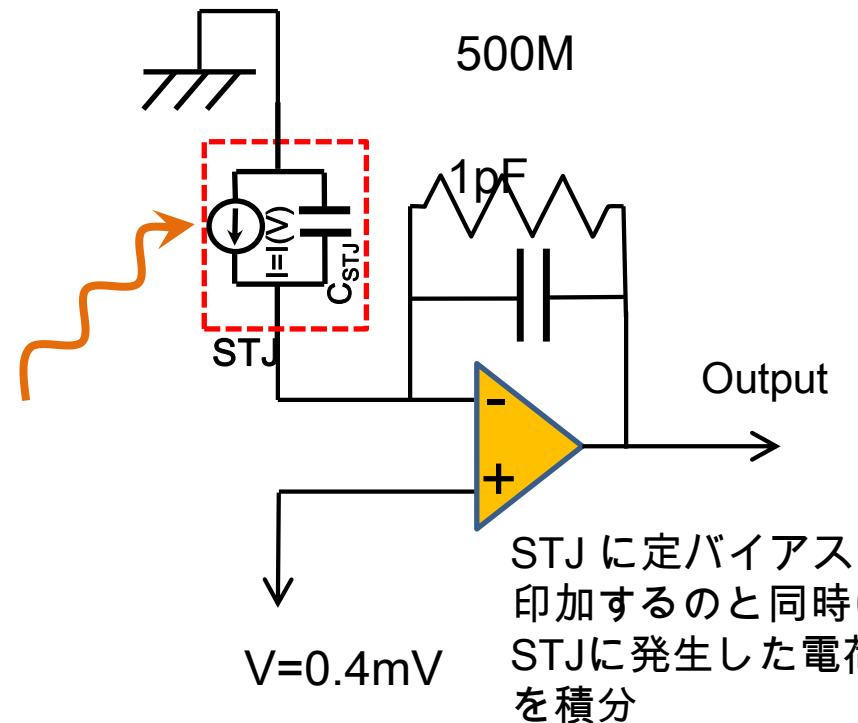

I-V curve of a STJ fabricated at KEK on a FD-SOI wafer

- Both nMOS and pMOS-FET in FD-SOI wafer on which a STJ is fabricated work fine at temperature down below 1K
 - 極低温では、スレッショルド電圧のシフト、サブスレッショルド領域のドレイン電流抑制、飽和領域でのドレイン電流の上昇など、特性が変動
- Nb/AI-STJ fabricated at KEK on FD-SOI works fine
- We are also developing SOI-STJ where STJ is fabricated at CRAVITY

SOI Pre-amplifier development

- 遠赤外一光子検出に向け，前段階として近赤外一光子検出に最適化した電荷積分型アンプをVDEC* が提供するSPICE simulation で設計中
- 極低温での SOI MOSFET の振る舞いをシミュレーションに組み込むため KEK や JAXA と共同研究で SPICE用MOSFETパラメータを構築中
 - 様々なL(チャンネル長 : L=0.4~5um)やW(チャンネル幅: W=1~10um)を持ったFETの3Kにおける特性の測定

室温でのFET パラメータを仮定したSPICE simulation
入力電荷:2fC
1.3eV(波長1μm)の一光子入射相当

* VLSI Design and Education Center(VDEC), the U. Tokyo in collaboration with Synopsys, Inc., Cadence Design Systems, Inc., and Mentor Graphics, Inc.

まとめ

- 遠赤外(50μm)の一光子検出が可能な検出器を STJ + SOI の技術を用いて開発中
 - 光子計数により，実効的にNEP で $\sim 10^{-20}W/\sqrt{Hz}$ を目指す
- Nb/AI-STJ は，産総研CRAVITY で世界最高水準の低リーク電流のものが得られている(<200pA @ 50μm角)
 - 20μm角，10μm角のものもテスト中
- SOIに技術を用いた極低温アンプによる読み出し回路を開発中
 - 様々なW/LをもつSOI MOSFETの極低温でのI-V測定→SPICE シミュレーションにもちいるFETパラメータ抽出
 - 光子計数の利点を最大限に生かす高速アンプ(帯域>1MHz)
 - SOI アンプ一体型STJの可能性

Backup

Neutrino

- Neutrino has 3 mass generations (ν_1, ν_2, ν_3)
- Neutrino flavor states (ν_e, ν_μ, ν_τ) are not mass eigenstates

$$\begin{pmatrix} \nu_e \\ \nu_\mu \\ \nu_\tau \end{pmatrix} = \begin{pmatrix} U_{e1} & U_{e2} & U_{e3} \\ U_{\mu 1} & U_{\mu 2} & U_{\mu 3} \\ U_{\tau 1} & U_{\tau 2} & U_{\tau 3} \end{pmatrix} \begin{pmatrix} \nu_1 \\ \nu_2 \\ \nu_3 \end{pmatrix}$$

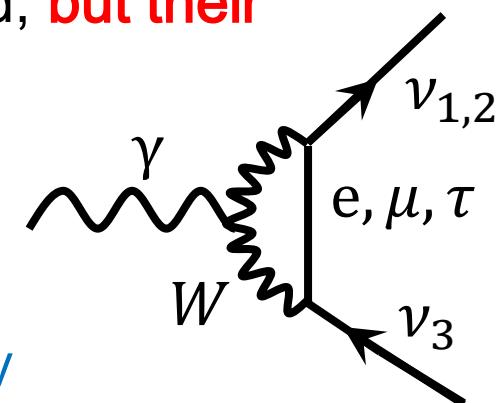

→ Neutrino flavor oscillates during the flight, and squared mass differences ($\Delta m_{12}^2, |\Delta m_{23}^2|$) have been measured, **but their absolute masses are not measured yet!**

□ **Heavier neutrinos (ν_2, ν_3) are not stable**

- Neutrino can decay through the loop diagrams
- $\nu_3 \rightarrow \nu_{1,2} + \gamma$
- Neutrino mass can be determined from the decay

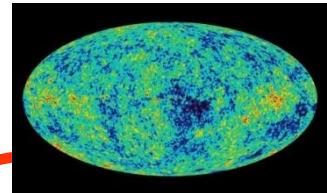

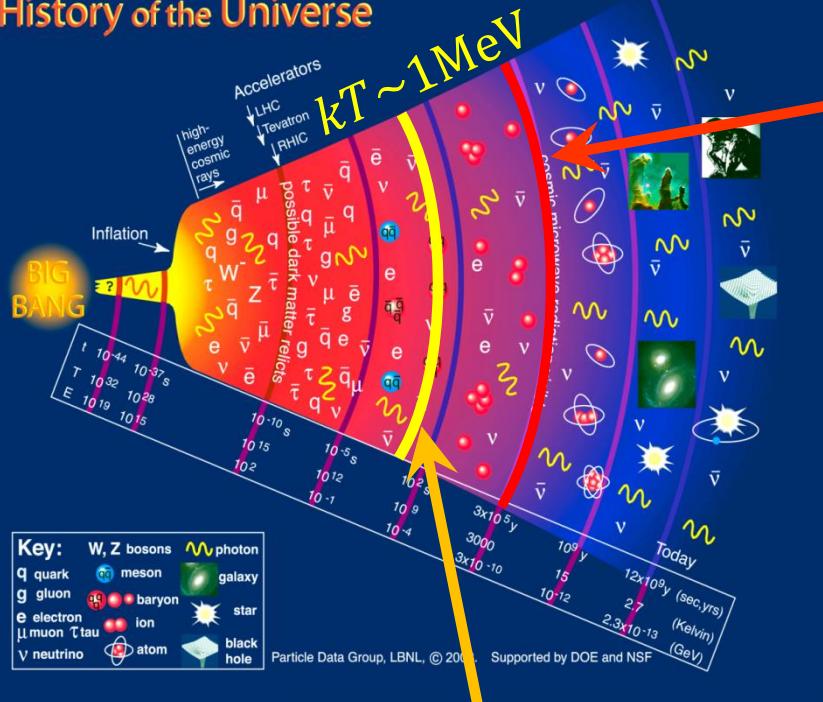

✓ However, neutrino lifetime is expected to be very long (much longer than the age of universe)

→ We adopt Cosmic neutrino background (CvB) as the neutrino source for neutrino decay search

Cosmic neutrino background (CνB)

History of the Universe

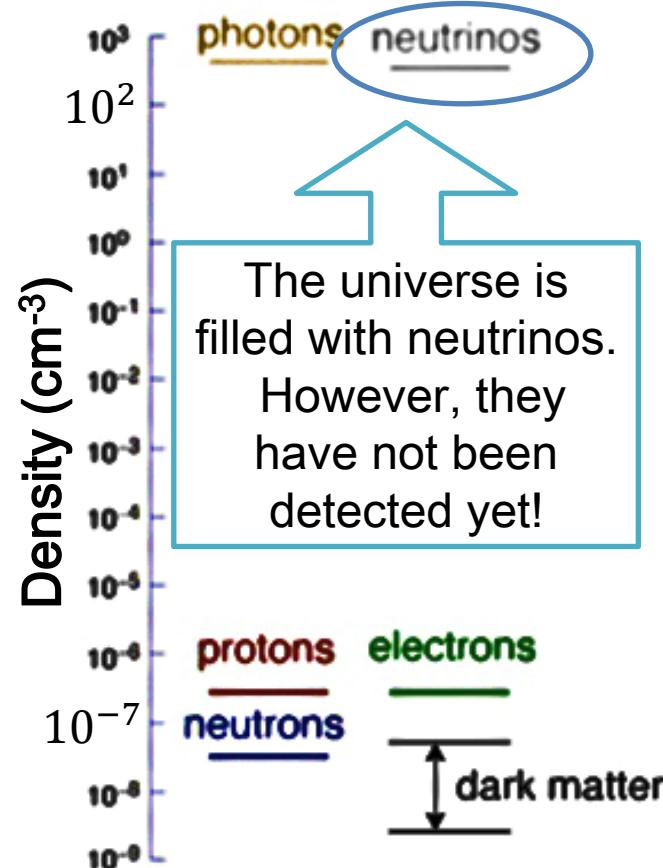

CMB

$$n_\gamma = 411/\text{cm}^3$$

$$T_\gamma = 2.73 \text{ K}$$

The Particle Universe

CνB (=neutrino decoupling)
~1s after the big bang

$$T_\nu = \left(\frac{4}{11}\right)^{\frac{1}{3}} T_\gamma = 1.95 \text{ K}$$

$$\langle p_\nu \rangle = 0.5 \text{ meV/c}$$

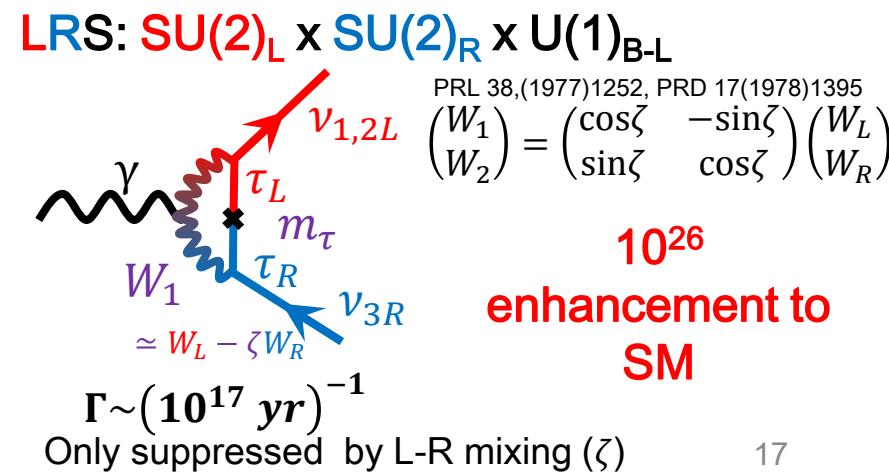

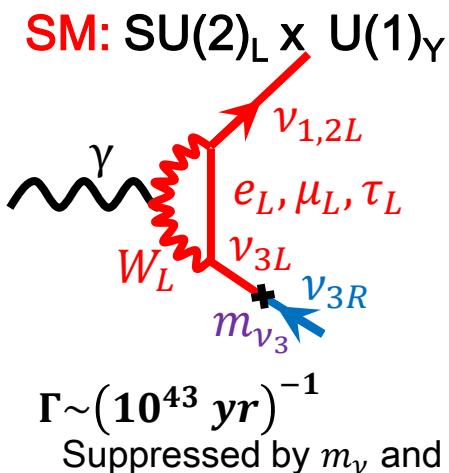

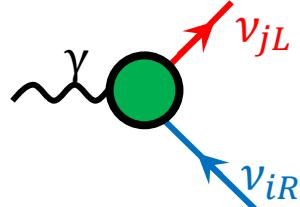

$$n_\nu + n_{\bar{\nu}} = \frac{3}{4} \left(\frac{T_\nu}{T_\gamma}\right)^3 n_\gamma = 110/\text{cm}^3$$

Motivation of ν -decay search in C ν B

- Search for $\nu_3 \rightarrow \nu_{1,2} + \gamma$ in cosmic neutrino background (C ν B)
 - Search for anomalous magnetic moment of neutrino
 - Direct detection of C ν B
 - Determination of neutrino mass: $m_3 = (m_3^2 - m_{1,2}^2)/2E_\gamma$
- Aiming at a sensitivity to ν lifetime for $\tau(\nu_3) = O(10^{17}\text{ yrs})$
 - Standard Model expectation: $\tau = O(10^{43}\text{ yrs})$
 - Experimental lower limit: $\tau > O(10^{12}\text{ yrs})$
 - L-R symmetric model (for Dirac neutrino) predicts down to $\tau = O(10^{17}\text{ yrs})$ for W_L - W_R mixing angle $\zeta < 0.02$

Magnetic moment term
(need L-R coupling)

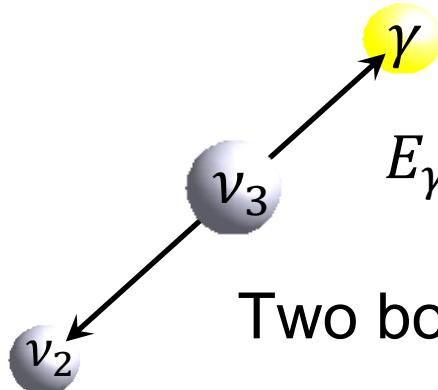

$$\bar{\nu}_{jL} i\sigma_{\mu\nu} q^\nu \nu_{iR}$$

Photon Energy (Wavelength) in Neutrino Decay

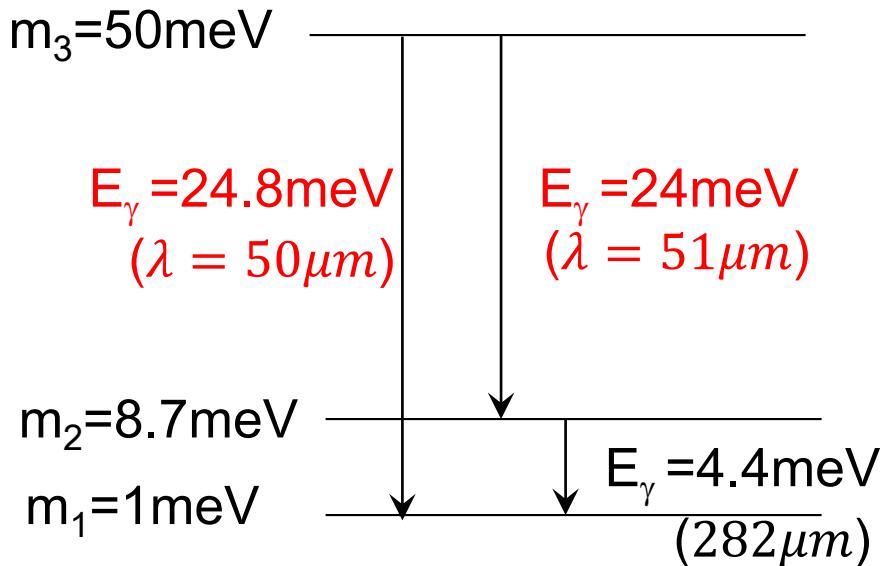

$$\nu_3 \rightarrow \nu_{1,2} + \gamma$$

in the ν_3 rest frame

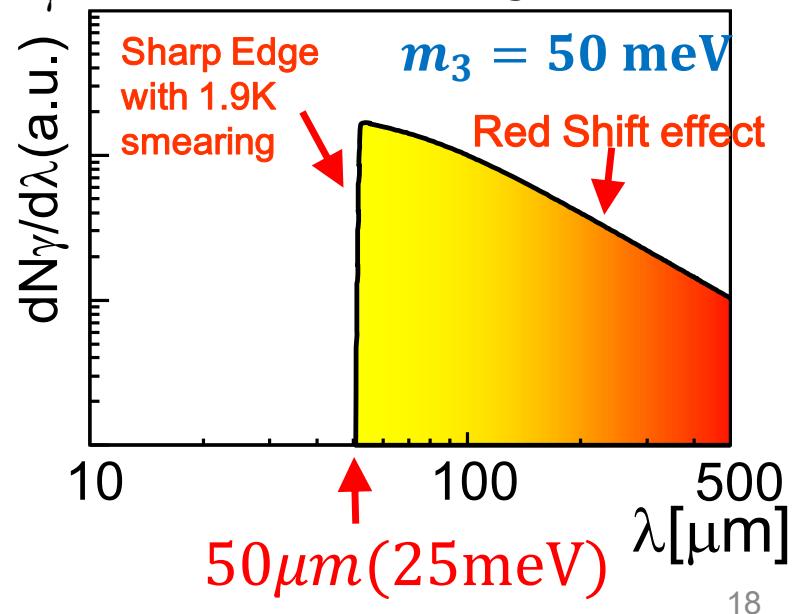

$$E_\gamma = \frac{m_3^2 - m_{1,2}^2}{2m_3}$$

Two body decay

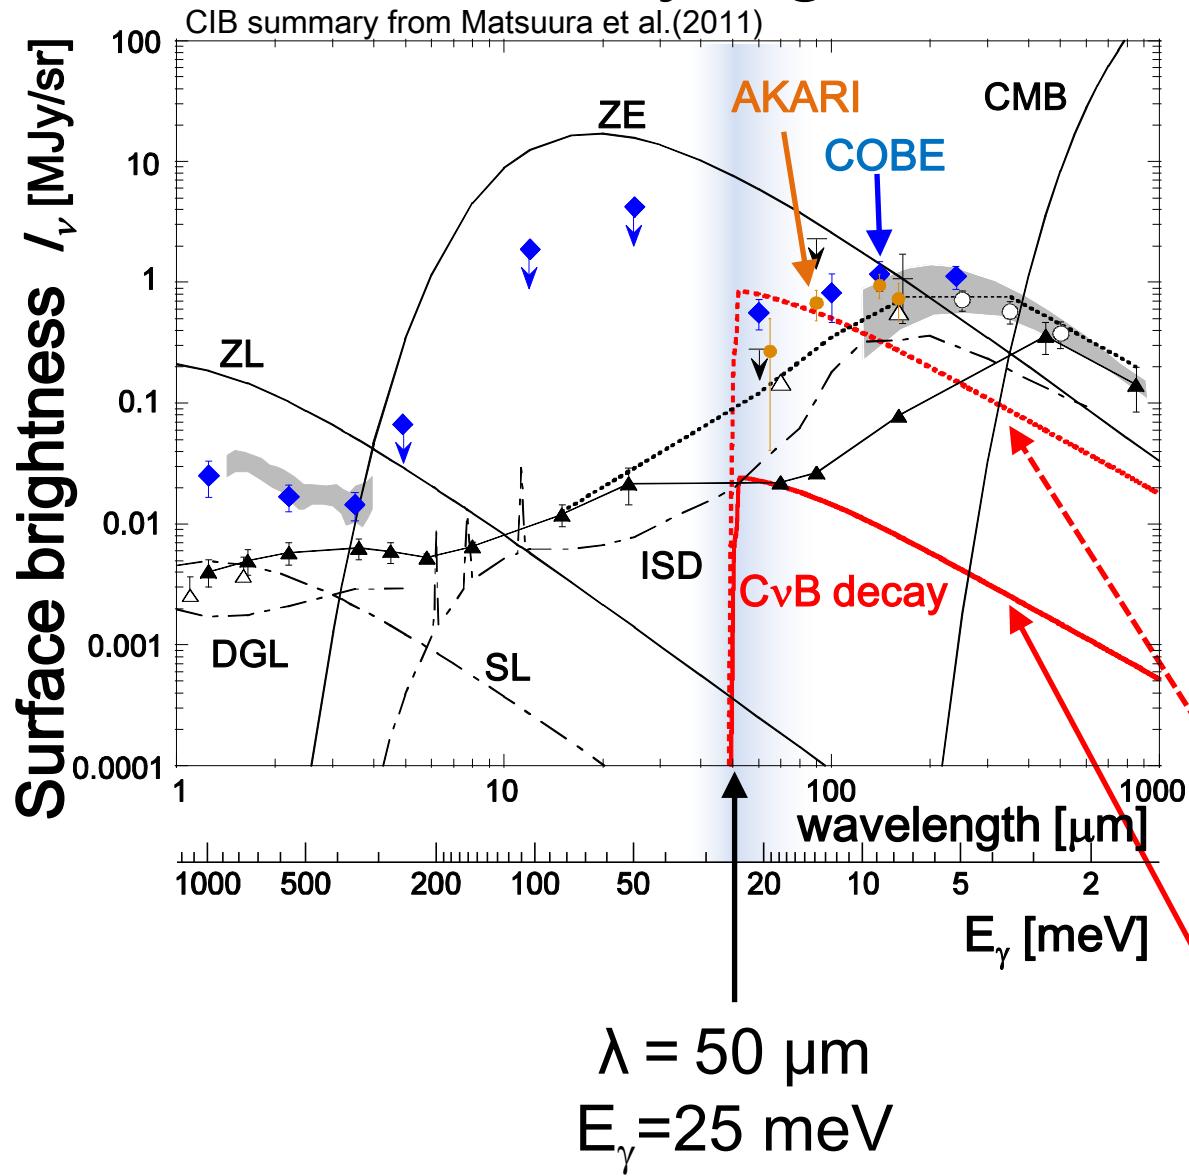

- From neutrino oscillation
 - $|\Delta m_{23}^2| = |m_3^2 - m_2^2| \sim 2.4 \times 10^{-3} \text{ eV}^2$
 - $\Delta m_{12}^2 \sim 7.65 \times 10^{-5} \text{ eV}^2$
 - From Planck+WP+highL+BAO
 - $\sum m_i < 0.23 \text{ eV}$
- $50\text{meV} < m_3 < 87\text{meV}$
- $E_\gamma^{\text{rest}} = 14 \sim 24\text{meV}$ ($\lambda_\gamma = 51 \sim 89\mu\text{m}$)

λ_γ distribution in $\nu_3 \rightarrow \nu_2 + \gamma$

$C\nu B$ decay signal and Backgrounds

at $\lambda = 50\mu\text{m}$

Zodiacal Emission(ZE)

$$I_\nu \sim 8 \text{ MJy/sr}$$

CIB

$$\lambda I_\lambda \sim 0.1-0.5 \text{ MJy/sr}$$

$C\nu B$ decay

Expected E_γ spectrum
 $m_3 = 50\text{meV}$

$$\tau = 3 \times 10^{12} \text{ yrs}$$

$$I_\nu \sim 0.8 \text{ MJy/sr}$$

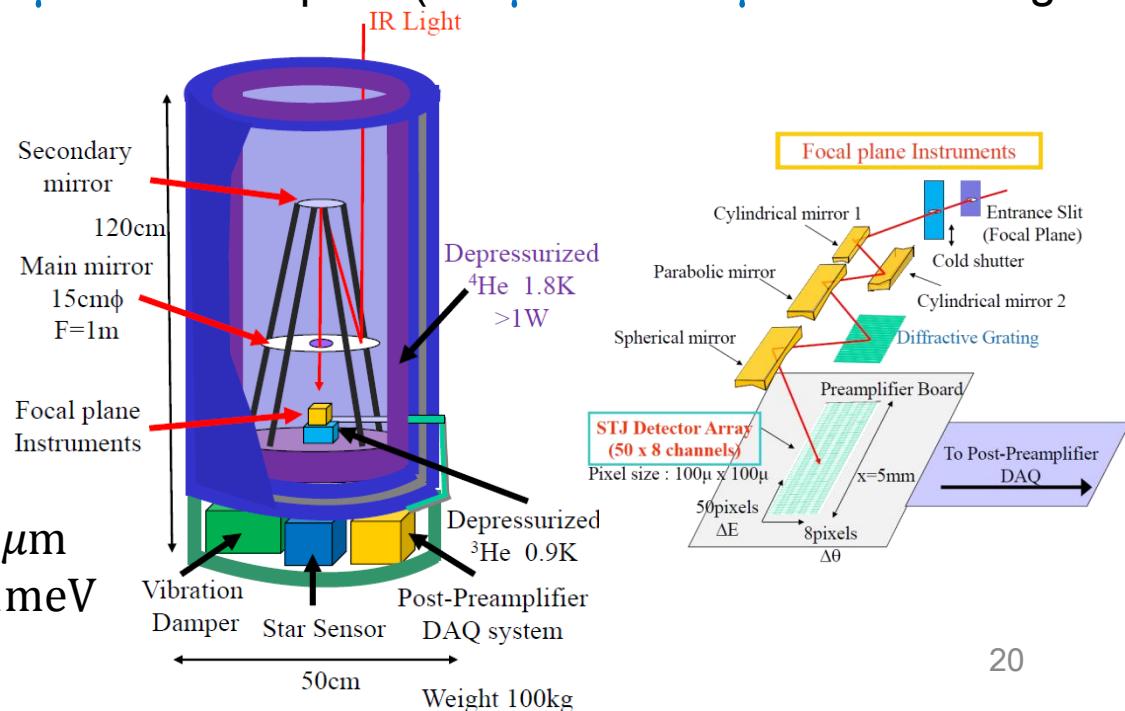

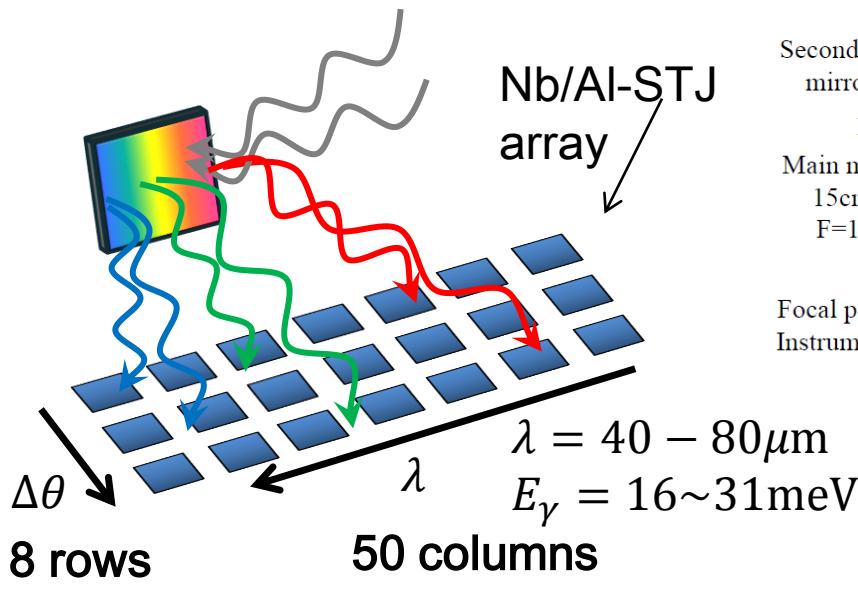

Excluded by S.H.Kim et. al 2012

$$\tau = 1 \times 10^{14} \text{ yrs}$$

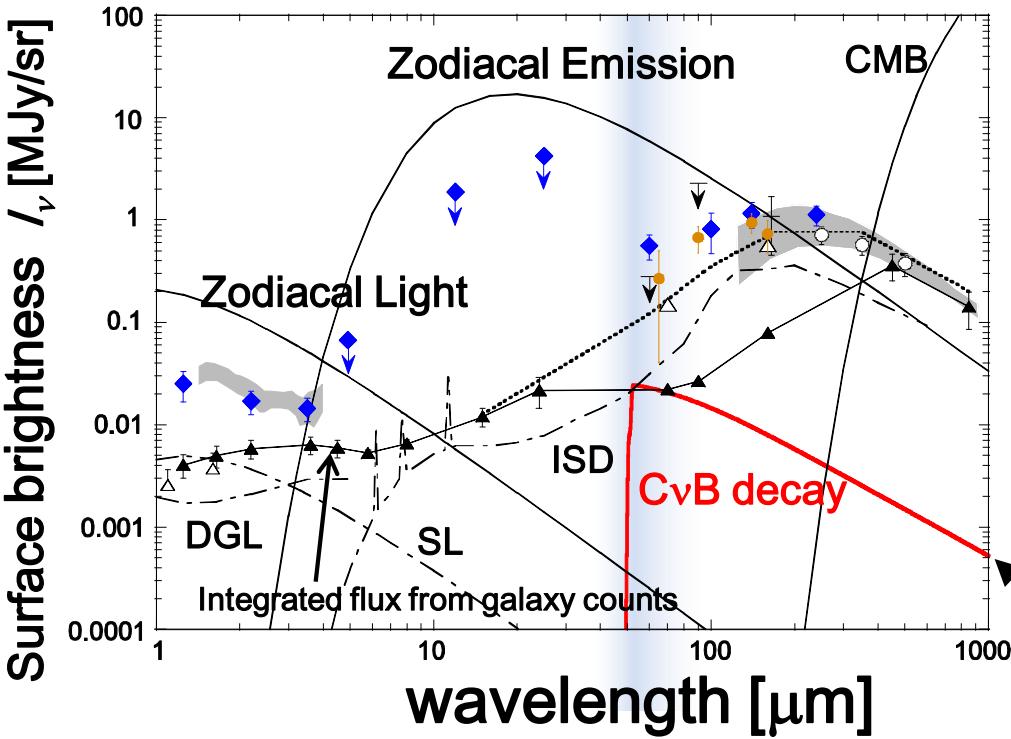

$$I_\nu \sim 25 \text{ kJy/sr}$$

Proposed rocket experiment with a diffraction grating and Nb/Al-STJ array combination

- 200-sec measurement at altitude of 200~300km
 - Telescope with **diameter of 15cm** and **focal length of 1m**
 - All optics (mirrors, filters, shutters and grating) will be cooled at ~1.8K
- At the focal point, diffraction grating covering $\lambda=40\text{-}80\mu\text{m}$ ($16\text{-}31\text{meV}$) and array of Nb/Al-STJ pixels of **50(in wavelength distribution) x 8(in spatial distribution)** are placed
 - Each Nb/Al-STJ pixel is used as **a single-photon counting detector** for FIR photon in $\lambda=40\text{-}80\mu\text{m}$ ($\Delta\lambda = 0.8\mu\text{m}$)
 - Sensitive area of $100\mu\text{m}\times 100\mu\text{m}$ for each pixel ($100\mu\text{rad} \times 100\mu\text{rad}$ in viewing angle)

Expected precision in the spectrum measurement

Telescope parameters

- Main mirror
 - $D=15\text{cm}$, $F=1\text{m}$
 - detector
 - sensitive area $100\mu\text{m} \times 100\mu\text{m} / \text{pixel}$
 - 50×8 array
- $$\Delta\lambda = \frac{80\mu\text{m} - 40\mu\text{m}}{50} = 0.8\mu\text{m}$$

$$\tau = 1 \times 10^{14} \text{ yrs}$$

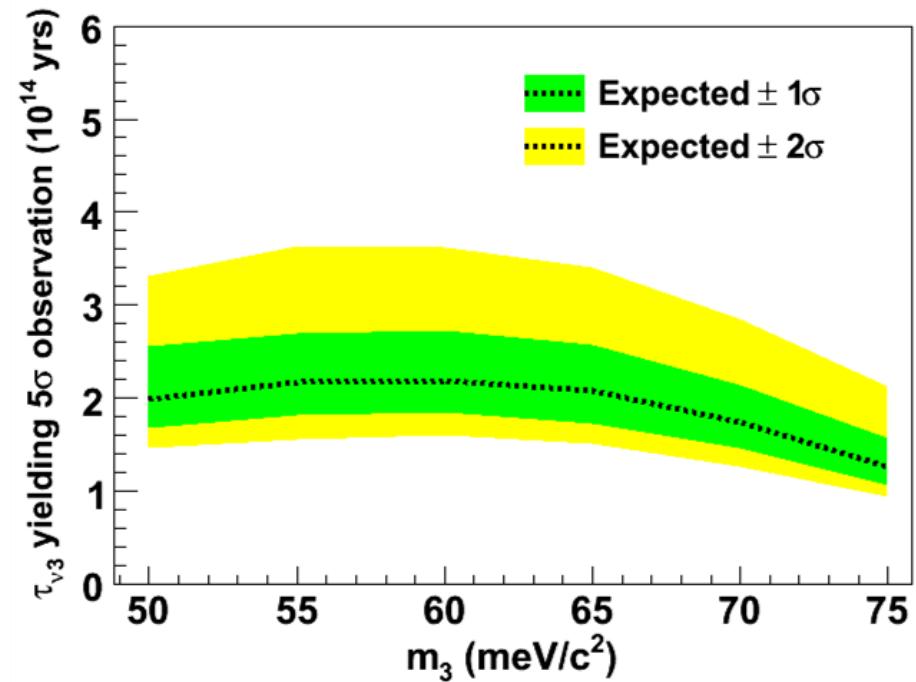

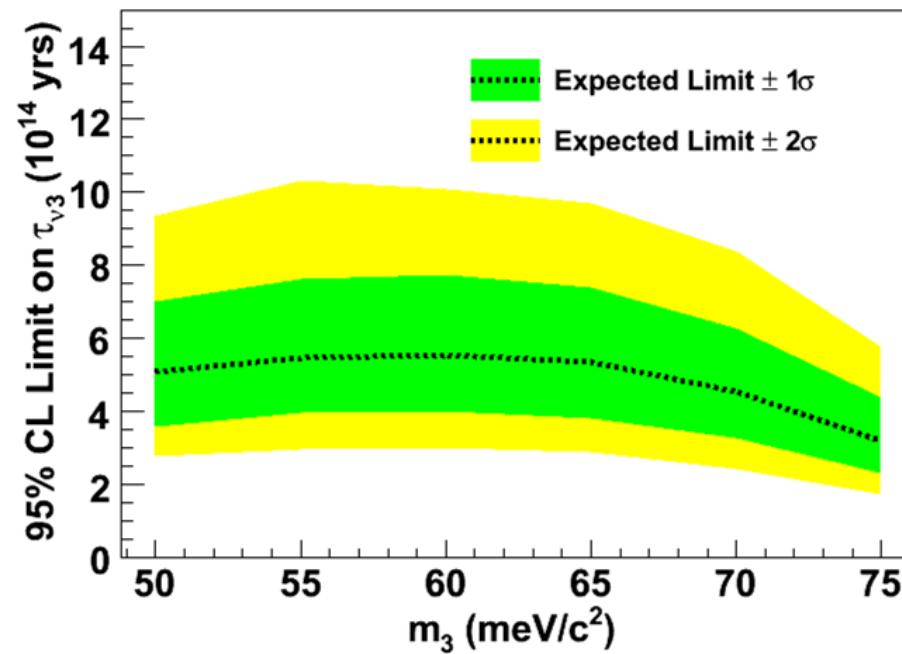

- Zodiacal emission $\Rightarrow 343\text{Hz} / \text{pixel}$
 - 200sec measurement: $0.55\text{M events} / 8 \text{ pixels}$ (at $\lambda = 50\mu\text{m}$)
 - 0.13% accuracy measurement for each wavelength: $\delta(I_\nu) = 11\text{kJy/sr}$
- Neutrino decay ($m_3 = 50 \text{ meV}$, $\tau_\nu = 1 \times 10^{14} \text{ yrs}$): $I_\nu = 25\text{kJy/sr}$
 - 2.3σ away from statistical fluctuation in ZE measurement

ν decay with $\tau_\nu = 10^{14}$ yrs is possible to detect, or set lower limit!

Sensitivity to neutrino decay

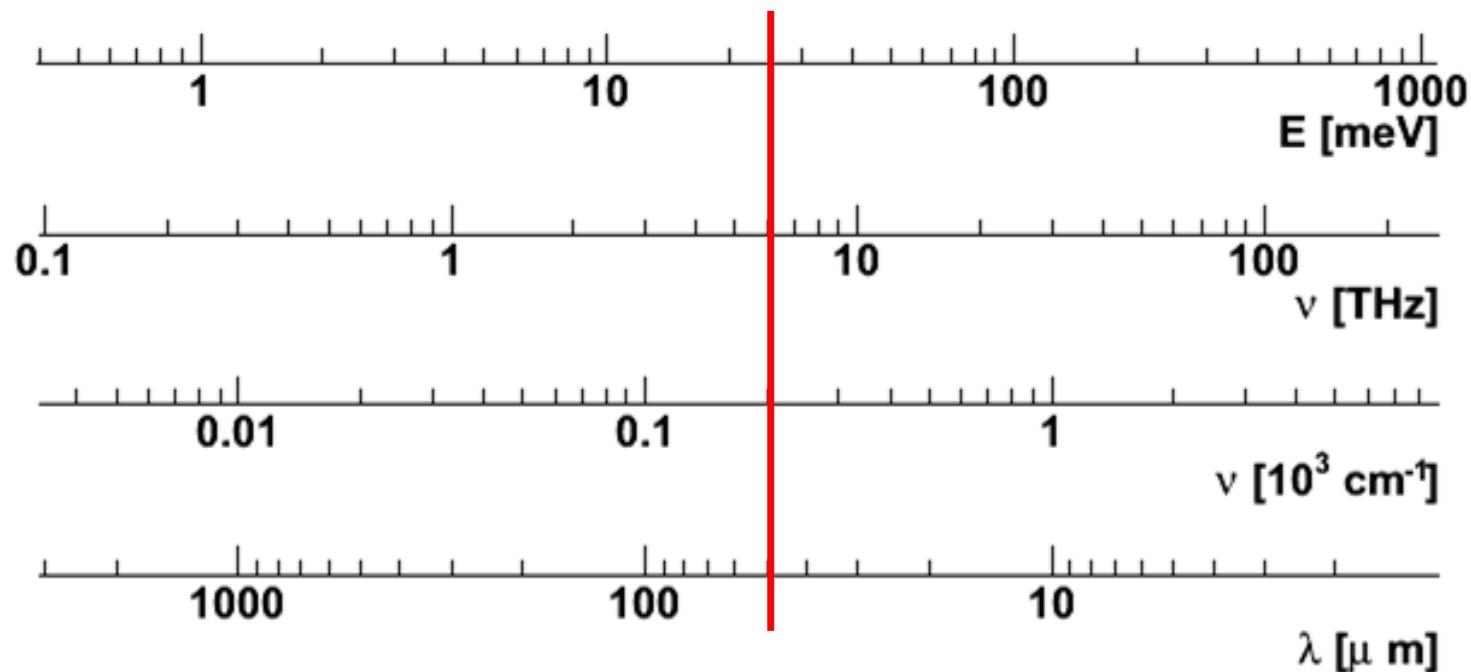

Parameters in the rocket experiment simulation

- telescope dia.: 15cm
- 50-column (λ : 40 μm – 80 μm) \times 8-row array
- Viewing angle per single pixel: 100 μrad \times 100 μrad
- Measurement time: 200 sec.
- Photon detection efficiency: 100%

- Can set lower limit on ν_3 lifetime at $4\text{--}6 \times 10^{14}$ yrs if no neutrino decay observed
- If ν_3 lifetime were 2×10^{14} yrs, the signal significance is at 5 σ level

Energy/Wavelength/Frequency

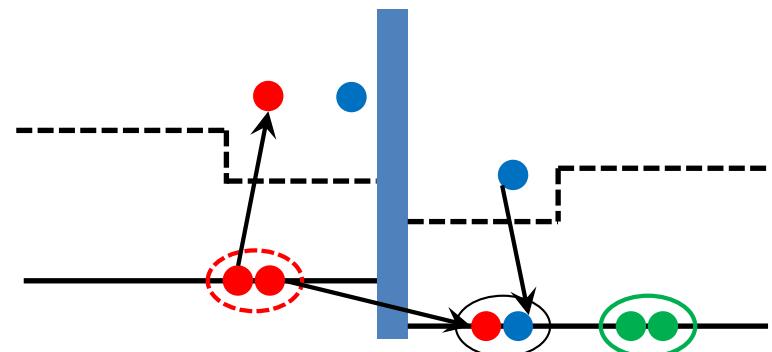

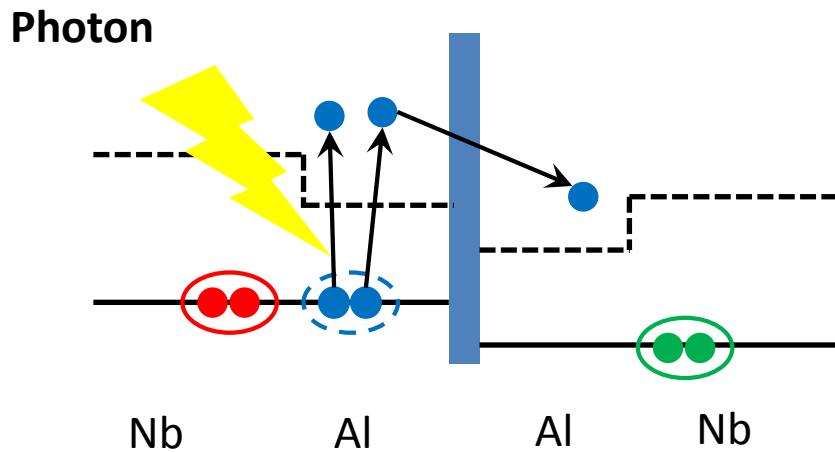

$$E_\gamma = 25 \text{ meV}$$

$$\nu = 6 \text{ THz}$$

$$\lambda = 50 \mu\text{m}$$

STJ back-tunneling effect

- Quasi-particles near the barrier can mediate Cooper pairs, resulting in true signal gain
 - Bi-layer fabricated with superconductors of different gaps $\Delta_{Nb} > \Delta_{Al}$ to enhance quasi-particle density near the barrier
 - Nb/Al-STJ Nb(200nm)/Al(10nm)/AlOx/Al(10nm)/Nb(100nm)
- Gain: $2 \sim 200$

STJ energy resolution

Statistical fluctuation in number of quasi-particles → energy resolution

→ Smaller superconducting gap energy Δ yields better energy resolution

$$\sigma_E = \sqrt{(1.7\Delta)FE}$$

Δ: Superconducting gap energy
F: fano factor
E: Photon energy

| | Si | Nb | Al | Hf |
|----------------|------|--------|--------|--------|
| Tc [K] | | 9. 23 | 1. 20 | 0. 165 |
| Δ [meV] | 1100 | 1. 550 | 0. 172 | 0. 020 |

Nb

Well-established as Nb/Al-STJ
(back-tunneling gain from Al-layers)

$$N_{q.p.} = 25 \text{ meV} / 1.7\Delta = 9.5$$

Poor energy resolution, but a single-photon detection is possible

Hf

Hf-STJ is not established as a practical photon detector yet

$$N_{q.p.} = 25 \text{ meV} / 1.7\Delta = 735$$

2% energy resolution is achievable if Fano factor < 0.3 for a single-photon

検出器に要求されるNEP

Telescope parameters

- Main mirror: D=15cm, F=1m
- detector
 - 波長 $0.8\mu\text{m}$ ($= (80\mu\text{m}-40\mu\text{m})/50$, $\Delta\nu=c/50\mu\text{m}-c/50.8\mu\text{m}=94\text{GHz}$)あたり
 $100\mu\text{m} \times 100\mu\text{m} \times 8 \text{ pixels} \rightarrow \text{視野角: } 8 \times 10^{-8} \text{ sr}$
- Neutrino decay ($m_3 = 50 \text{ meV}$, $\tau_\nu = 1 \times 10^{14} \text{ yrs}$): $I_\nu=25\text{kJy/sr} @ \lambda=50\mu\text{m}$
 $F_{\nu\gamma} = 25 \text{ kJy/sr} \times 8 \times 10^{-8} \text{ sr} \times \pi(15\text{cm}/2)^2 \times 94\text{GHz} = 3.3 \times 10^{-20} W/8pix$
- Zodiacal emission: $I_\nu=8\text{MJy/sr} @ \lambda=50\mu\text{m}$
 $F_{ZE} = 1.1 \times 10^{-17} W/8pix$
- Δt 時間で F_{ZE} 積分した際の揺らぎ
エネルギー- ε_γ のフォトン数揺らぎ起因 : $\epsilon_\gamma \sqrt{F_{ZE} \Delta t / \epsilon_\gamma} = \sqrt{\epsilon_\gamma F_{ZE} \Delta t}$
- 測定条件 , 検出器要件を決める不等式
$$NEP \times \sqrt{2\Delta t} < \sqrt{\epsilon_\gamma F_{ZE} \Delta t} < F_{\nu\gamma} \Delta t$$

$\rightarrow \Delta t > 40\text{sec (1}\sigma\text{)}, \Delta t > 200\text{sec (2.2}\sigma\text{)}$

$\rightarrow NEP < 1.5 \times 10^{-19} W/\sqrt{\text{Hz}}$ for $\Delta t = 200\text{sec}$ with 8 pix
